Spring 2008/ Lecture 11

# Distributed Operating Systems

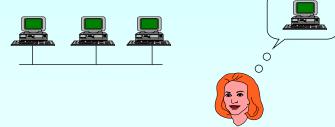

Lecture 11

Yair Amir & Raluca Musaloiu-E

Spring 2008/ Lecture 11

## A Distributed Operating System

An operating system which manages a collection of independent computers and makes them appear to the users of the system as a single computer.

Yair Amir & Raluca Musaloiu-E

Spring 2008/ Lecture 11

3

#### Hardware Architectures Parallel architecture Multiprocessors CPU CPU Memory - Tightly coupled. Cache Cache - Shared memory. Distributed architecture Multicomputers. Memory Memory Memory - Loosely coupled. CPU CPU CPU - Private memory. Autonomous. Yair Amir & Raluca Musaloiu-E Spring 2008/ Lecture 11

### Software Architectures

- Multiprocessor OS
  - Looks like a virtual uniprocessor, contains only one copy of the operating system, communication via shared memory, single run-queue
- Network OS
  - Does not look like a virtual uniprocessor, contains n copies of the operating system, communication via shared files, n run-queues
- Distributed OS
  - Looks like a virtual uniprocessor (more or less), contains n copies of the operating system, communication via messages, n run-queues

Yair Amir & Raluca Musaloiu-E Spring 2008/ Lecture 11

5

## Design Issues

- Transparency
  - Location (processes, cpu(s), files)
  - Replication of files
  - Parallelism
- Performance
  - Throughput / response time
  - Load balancing (static/dynamic)
  - Communication is slow compared to processing speed: Fine grain / coarse grain
- Scalability
- Reliability
- · Architecture flexibility.

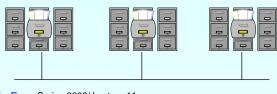

Yair Amir & Raluca Musaloiu-E

Spring 2008/ Lecture 11

## Distributed File Systems

- · File and directory naming
- · Semantics of file sharing
- · Implementation considerations
  - Caching
  - Update protocols
  - Replication

Yair Amir & Raluca Musaloiu-E

Spring 2008/ Lecture 11

## File and Directory Naming

- Machine + path naming /machine/path.
  - one name space, but not transparent.
- Mounting remote file systems onto the local file hierarchy.
  - The view of the file system may be different at each computer.
- A single name space that looks the same on all machines.
  - Full naming transparency.

Yair Amir & Raluca Musaloiu-E

Spring 2008/ Lecture 11

## File Sharing Semantics

- One-copy semantics (unix semantics).
  - Updates are written to the single copy and are available immediately.
- Serializability.
  - Transaction semantics (locking files share for read and exclusive for write).
- Session semantics.
  - Copy the file on open, work on local copy, and copy back on close.

Yair Amir & Raluca Musaloiu-E

Spring 2008/ Lecture 11

9

#### Sun-NFS

- Supports heterogeneous systems.
- Architecture
  - Server exports one or more directory trees for access by remote clients.
  - Clients access exported directory trees by mounting them to the client local tree.
  - Diskless clients can mount exported directory to their root directory.
  - Auto-mount (on the first access).

Yair Amir & Raluca Musaloiu-E

Spring 2008/ Lecture 11

## Sun-NFS (cont.)

#### Protocols

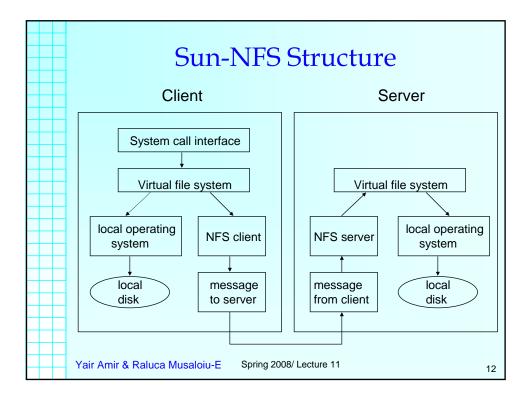

- Mounting protocol
- Directory and file accessing protocol
  - Stateless
  - No open / close messages.
  - Each read / write message contain the full path and file description position.

#### Semantics

- Not entirely Unix since there is no way to lock files
- Timing issues

Yair Amir & Raluca Musaloiu-E

Spring 2008/ Lecture 11

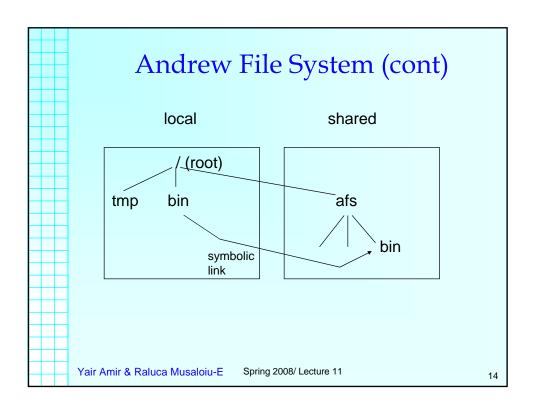

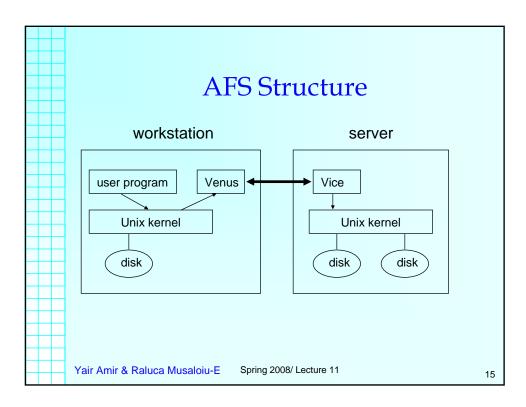

## Andrew File System

- Supports information sharing on a large scale (thousands of workstations).
- Uses session semantics.
- The entire file is copied to the local machine (Venus) from the server (Vice) when open. If the file is changed - it is copied to the server when closed.
- The method works because in practice most files are changed by one person only (non-database).
- Measurements show that only 0.4% of changed files were updated by more than one user during one week.

Yair Amir & Raluca Musaloiu-E

Spring 2008/ Lecture 11

### **AFS File Validation**

- Older AFS versions:
  - On open: the Venus access the vice to see if its copy of the file is still valid. This causes a substantial delay even if the copy is valid.
  - The Vice is stateless
- Newer AFS versions:
  - The Vice maintains lists of valid copies. If a file is modified, the Vice invalidates other copies.
  - On open: if the Venus has a valid copy it can open it immediately.
  - If Venus crashes it has to invalidate its version or check their validity.

Yair Amir & Raluca Musaloiu-E Spring 2008/ Lecture 11

## The Coda File System

- Descendant of AFS that is substantially more resilient to server and network failures.
- Support for "mobile" users.
- Directories are replicated in several servers (Vice)
- When the Venus is disconnected, it uses local versions of files. When Venus reconnects, it reintegrates using optimistic update scheme.

Yair Amir & Raluca Musaloiu-E

Spring 2008/ Lecture 11

17

## **Process Migration**

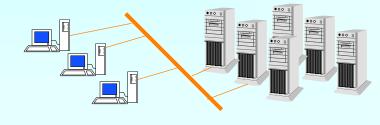

- Load Balancing
  - Static load balancing CPU is determined at process creation.
  - Dynamic load balancing processes dynamically migrate to other computers to balance the CPU (or memory) load.
- Migration architecture
  - One image system
  - Point of entrance dependent system (the deputy concept)

Yair Amir & Raluca Musaloiu-E

Spring 2008/ Lecture 11

### A Mosix Cluster

- Mosix: Kernel level enhancement to Linux that provides dynamic load balancing in a network of workstations.
- Dozens of PC computers connected by local area network (Fast-Ethernet and up).
- · Any process can migrate anywhere anytime.
- www.mosix.org

Yair Amir & Raluca Musaloiu-E

Spring 2008/ Lecture 11

19

## An Architecture for Migration

user level		user level		
system calls interface	system calls interfac			
communication				
lower kernel		lower kernel		

Architecture that fits one system image. Needs location transparent file system.

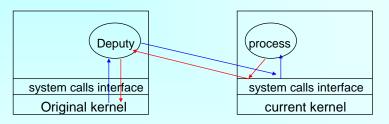

(Mosix previous versions)

Yair Amir & Raluca Musaloiu-E

Spring 2008/ Lecture 11

## Architecture for Migration (cont.)

The process migrated from the original computer to the current computer and now is initiating a system call.

- Architecture that fits entrance dependent system.
- Easier to implement based on current
   Unix. (Mosix current versions)

Yair Amir & Raluca Musaloiu-E

Spring 2008/ Lecture 11

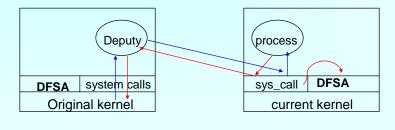

21

#### Mosix: File Access

Regularly, each file access must go back to deputy...

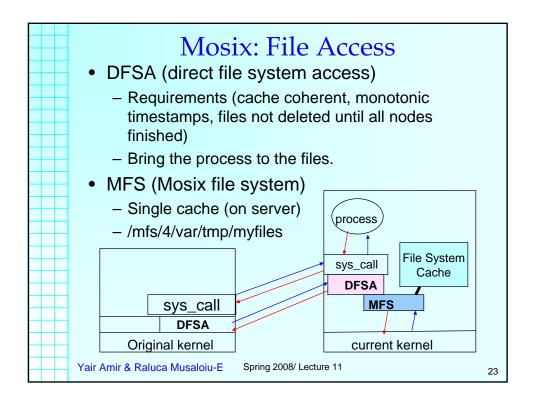

→ Very Slow for I/O apps.

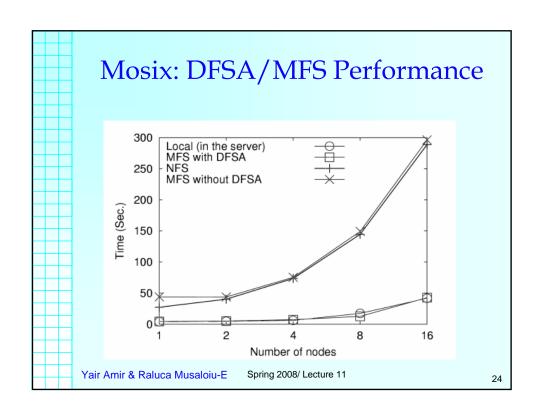

Solution-- Allow processes to access a distributed file system through the current kernel.

Yair Amir & Raluca Musaloiu-E

Spring 2008/ Lecture 11

## Other Considerations for Migration

- Not only CPU load!!!
- Memory.
- I/O where is the physical device?
- Communication which processes communicate with which other processes ?

Yair Amir & Raluca Musaloiu-E

Spring 2008/ Lecture 11

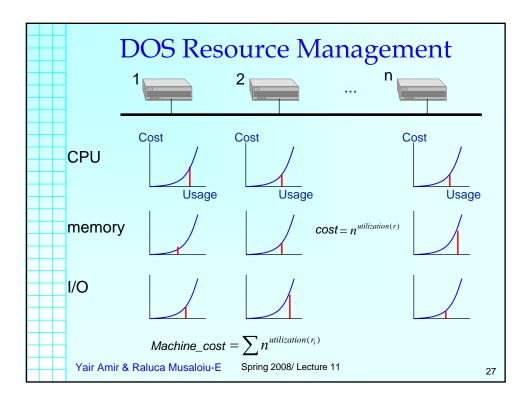

25

## Resource Management of DOS

- A new online job assignment policy based on economic principles, competitive analysis.
- Guarantees near-optimal global lower-bound performance.
- Converts usage of heterogeneous resources (CPU, memory, IO) into a single, homogeneous cost using a specific cost function.
- Assigns/migrates a job to the machine on which it incurs the lowest cost.

Yair Amir & Raluca Musaloiu-E

Spring 2008/ Lecture 11

## Case Study - PVM and MOSIX

- PVM Parallel Virtual Machine
  - Static Assignment of jobs to machines.
  - Default round robin assignment policy.
  - Widely used.

#### Mosix

- Dynamic job migration.
- Main objective is load balancing, with some adhoc heuristics for memory depletion.

Yair Amir & Raluca Musaloiu-E Spring 20

Spring 2008/ Lecture 11

## Enhanced PVM and Enhanced Mosix

- Enhanced PVM is similar to PVM. The decision where to statically place a new job is made according to the cost benefit framework.
- Enhanced Mosix is similar to Mosix. Job migration decisions are made according to the cost-benefit framework.

#### This framework takes into account:

- CPU load
- Memory utilization

Easy to add I/O. Harder to add IPC.

Yair Amir & Raluca Musaloiu-E

Spring 2008/ Lecture 11

29

## **Evaluation Methodology**

#### • Cluster:

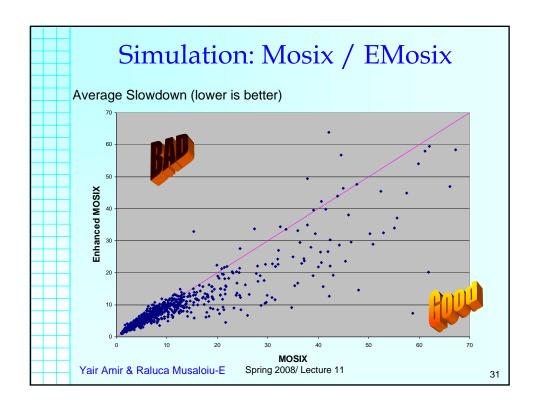

Machine Type	# of these Machines	Processing Speed	Installed Memory
Pentium Pro	3	200 MHz.	64 MB of RAM
Pentium	2	133 MHz.	32 MB of RAM
Laptop w/ Ethernet	1	90 MHz.	24 MB of RAM.

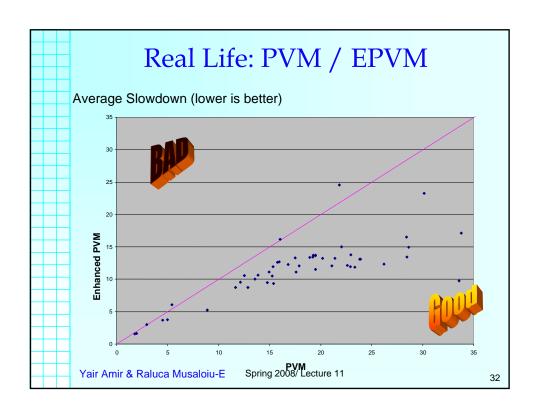

#### Simulation:

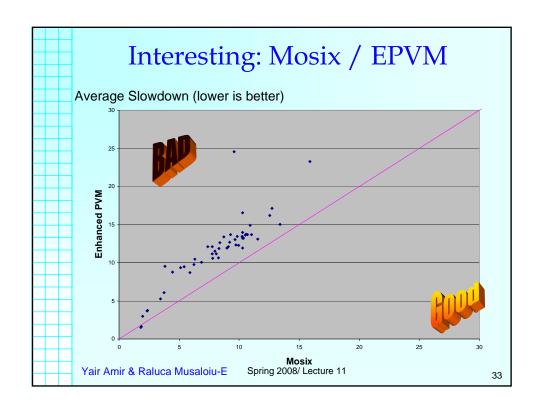

- 3,000 identical executions (scenarios) per policy, each represents 10,000 - 20,000 sec.
- Validation (real life executions):
  - 50 identical executions per policy (similar to the simulations).

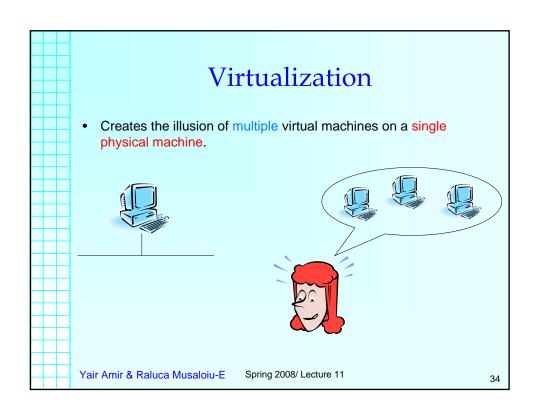

Yair Amir & Raluca Musaloiu-E

Spring 2008/ Lecture 11

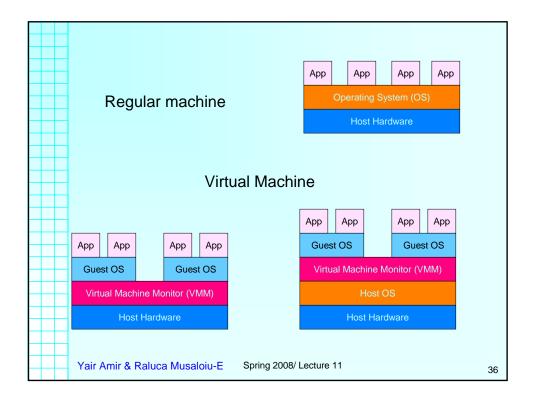

## Why Virtualize?

- Security
- Reliability and availability
- Cost
- · Load balancing
- Legacy applications

Yair Amir & Raluca Musaloiu-E

Spring 2008/ Lecture 11

## Virtualization through Emulation

- VM emulates complete hardware.
- Allows unmodified guest OS for a different PC to be run.

**Bochs** 

Microsoft Virtual PC for Mac

Yair Amir & Raluca Musaloiu-E

Spring 2008/ Lecture 11

37

## Full / Native Virtualization

- VM simulates enough hardware to allow an unmodified guest OS to be run in isolation.
- · Host and guest architectures are the same.

Mac-on-Linux

Yair Amir & Raluca Musaloiu-E

Spring 2008/ Lecture 11

## Paravirtualization

- Virtual hardware architecture differs from the underlying physical architecture.
- VMM presents a software interface to the guest OS. Guest OS must be modified to use VMM interface.
- · Does not require changes to the application.

VMware
Infrastructure
• ESX Server 3
• ESX Server 3i

Yair Amir & Raluca Musaloiu-E

Spring 2008/ Lecture 11

39

## OS Level Virtualization

- No guest OS. Host and VMs share the same kernel.
- No need to manage the OS.

(used by PlanetLab)

Yair Amir & Raluca Musaloiu-E

Spring 2008/ Lecture 11

## **Application Level Virtualization**

- Create isolated virtual environments to deploy and execute applications.
- Applications need to be packed for virtualization environment.

Yair Amir & Raluca Musaloiu-E

Spring 2008/ Lecture 11

41

## Virtualization in the Past

- Long time ago (more than 30 years): IBM VM/370.
- 80's: the cost of the hardware decreased, making the virtualization less interesting (moved away from mainframes).

Yair Amir & Raluca Musaloiu-E

Spring 2008/ Lecture 11

## Virtualization today: Server Consolidation

- Need for application isolation. Run one application per server.
- Lots of underutilized hardware (estimated resource utilization is 10-15%).

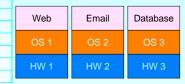

Yair Amir & Raluca Musaloiu-E

Spring 2008/ Lecture 11

43

## Server Consolidation

 Use virtualization to utilize physical resources as efficiently as possible.

Less hardware, space, power consumption.

Yair Amir & Raluca Musaloiu-E

Spring 2008/ Lecture 11

## Beyond Server Consolidation: Application Deployment

- Traditional approach: predict resource usage, acquire and release resources (servers acquisition can take months!).
- Use virtualization to provide a uniform application deployment environment for developers.
- Applications and OS are no longer tied to the physical hardware. Basic deployment unit is now the VM.
- VMs can be dynamically moved based on their resource requirements.

Yair Amir & Raluca Musaloiu-E

Spring 2008/ Lecture 11

45

## **Even more: Utility Computing**

- No need to own the hardware. Instead, pay only what you use!
- Computing and Storage is used as a service.
- Example: Amazon EC2, Amazon S3
  - 10¢ for for 1 EC2 Compute Unit (1 hour equivalent CPU capacity of a 1.0-1.2 GHz 2007 Opteron or 2007 Xeon processor).

Yair Amir & Raluca Musaloiu-E

Spring 2008/ Lecture 11

## Challenges

- How to accurately characterize applications' resource requirements.
  - What and how much: CPU, memory, disk, network utilization...
  - Resource usage may vary over time.
- How to distribute the VMs over the physical resources.
  - Various strategies: keep VMs together, separate VMs.

Yair Amir & Raluca Musaloiu-E

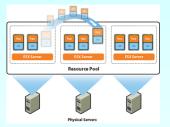

Spring 2008/ Lecture 11

47

## Challenges (2)

 How to balance the server workloads at runtime (migrate VM to another physical server).

#### **VMWare DRS**

- · Resource pools.
- Automate hardware maintenance.
- · Manual or automatic mode.
- Power management.
